Contents

1 Overview

This document presents an overview of the `aCGH` package, which provides wide basic functions for reading, analyzing and plotting array Comparative Genomic Hybridization data (Snijders et al. (2001)). Specific example for reading data in is using output of the custom freely available programs, SPOT and SPROC (Jain et al. (2002)). These programs provide image quantification and pre-processing. Outputs of all the other image processing software need to be combined into a single file containing observed values for each clone and samples and then read in as a matrix.

2   Data

The data used in the example was generated in in lab of Dr. Fred Waldman at UCSF Comprehensive Cancer Center (Nakao et al. (2004)).Array CGH has been done on 125 colorectal fresh-frozen primary tumors and the associations with various phenotypes were analyzed. To reduce running time, only 40 samples are used in the examples.

3   Examples

3.1   Creating aCGH object from log2.ratios and clone info files

Each array CGH object has to contain the log2ratios representing relative copy number along with the mapping information including but not limited to clone name, chromosome and kb relative to the chromosome. Optionally there may be phenotypes associated with each sample.

```

Loading required package: sma

Attaching package: 'aCGH'

        The following object(s) are masked from package:stats :

         heatmap

> datadir <- system.file(package = "aCGH")
> datadir <- paste(datadir, "/examples", sep = "")
> clones.info <- read.table(file = file.path(datadir, "clones.info.ex.txt"),
+     header = T, sep = "\t", quote = "", comment.char = "")
> log2.ratios <- read.table(file = file.path(datadir, "log2.ratios.ex.txt"),
+     header = T, sep = "\t", quote = "", comment.char = "")
> pheno.type <- read.table(file = file.path(datadir, "pheno.type.ex.txt"),
```

```
+       header = T, sep = "\t", quote = "", comment.char = "")
> ex.acgh <- create.aCGH(log2.ratios, clones.info, pheno.type)
```

Note that when working with your own data, you will need to specify absolute path to those files ot the path relative to your working folder. For instance, if you are working in the folder *Project1* your data files are placed in the subfolder *Project1/Data*, then *datadir = "Data"* if you are using relative path.

3.2 Filtering and imputation for objects of class aCGH

Here we remove unmapped clones and clones mapping to Y chromosome, screen out clones missing in more than 25

```
> ex.acgh <- aCGH.process(ex.acgh, chrom.remove.threshold = 23,
+       prop.missing = 0.25, sample.quality.threshold = 0.4, unmapScreen = TRUE,
+       dupRemove = FALSE)
```

Here we impute missing observations using lowess approach. Note that occasionally, majority of the observations on chromosome Y may be missing causing imputing function to fail. Therefore, by default, the largest chromosome to be imputed is indexed as maxChrom=23 (X). Here we specify imputation for all chromosomes ; however, in this example there are no data on chromosome Y.

```
> log2.ratios.imputed(ex.acgh) <- impute.lowess(ex.acgh, maxChrom = 24)

3.4 Reading Sproc files

Here we demonstrate reading of the sproc files and combining them into one array CGH object. Sproc file format is specific to the custom SPROC processing software at UCSF Cancer Center.

```
> datadir <- system.file("examples", package = "aCGH")
> latest.mapping.file <- file.path(datadir, "human.clones.info.Jul03.txt")
> ex.acgh <- aCGH.read.Sprocs(dir(path = datadir, pattern = "sproc",
+     full.names = TRUE), latest.mapping.file, chrom.remove.threshold = 23)

3.6 Subsetting example

```
> cr <- colorectal[, 1:3]
```

3.7 Basic plot for the ordered log2 ratios along the genome

The relative copy number is plotted along the genome with clones placed in the genomic order. We are plotting sample 2 here. (fig. 3). Chromosome Y is explicitely excluded.

```
> plotGenome(ex.acgh, samples = 2, Y = FALSE)
```

Figure 3: Basic plot for the ordered log2 ratios along the genome

3.8 Computing and plotting hmm states

Unsupervised hidden markov model is repeatedly fitted to each chromosome for varying number of states (2 , ..., 5). The number of states is determined after all fits are done usingmodel selection criterion such as AIC, BIC or delta-BIC. The model with minimal penalized negative log-likelihood is chosen for each selection criterion. Note, that some of the model fits are going to fail and are not going to be used in the final selection. Meanwhile , error message warning of the model fit failing will be printed during hmm runs. The user shoulld ignore those particular messages and related warnings.

For a given sample, each chromosome is plotted on a separate page along with its smoothed values(fig. 4). The genomic events such as transitions, focal aberrations and amplifications are indicated. The outliers are also marked.

```
> hmm(ex.acgh) <- ex.acgh.hmm
> hmm.merged(ex.acgh) <- mergeHmmStates(ex.acgh, model.use = 1,
+     minDiff = 0.25)
> sd.samples(ex.acgh) <- computeSD.Samples(ex.acgh)
> genomic.events(ex.acgh) <- find.genomic.events(ex.acgh)

3.9   Plotting summary of the tumor profiles

Here the distribution of various genomic events as well as their frequency by location is displayed. Run the function plotSummaryProfile(colorectal) which produces multi-page figure. Necessary to write out as ps or pdf files.

3.10   Overall frequency plot (fig. 5)

```
> plotFreqStat(colorectal, all = T)
```

Figure 5: Overall frequency plot of the tumor profiles

summarize.clones() function is the text equivalent of plotFreqStat() - it summarizes the frequencies of changes for each clone across tumors and includes results of statistical comparisons for each clone when available.

```
> summarize.clones(colorectal)[1:10, ]
```

3.11 Testing association of clones with categorical, censored or continuous outcomes.

Use mt.maxT function from multtest package to test differences in group means for each clone grouped by sex. Plot the result along the genome displaying the frequencies of gains and losses as well well as height of the statistic correponsding to each clone(figs. 6 and 7.). The p-value can be adjusted and the horizontal lines indicate chosen level of significance.

Figure 7: Plotting summary of the tumor profiles

Testing association of clones with categorical outcome for autosomal clones that are gained or lost in at least 10% of the samples. Note that the same dataset should be provided for creating *resT* object and for plotting. Pay attention that HMM-related objects including sample variability do not get subsetted at the moment. Note that currently two-stage subsetting does not work for HMM slots, i.e. two conditions (change and autosomal) need to be done in one iteration.

```
> factor <- 3
> minChanged <- 0.1
> gainloss <- gainLoss(log2.ratios(colorectal)[, sex.na], cols = 1:length(which(sex.na)),
+     thres = (factor * (sd.samples(colorectal)$madGenome))[sex.na])
> ind.clones.use <- which(gainloss$gainP >= minChanged | gainloss$lossP >=
+     minChanged & clones.info(colorectal)$Chrom < 23)
> colorectal.na <- colorectal[ind.clones.use, sex.na, keep = TRUE]
> dat <- log2.ratios.imputed(colorectal.na)
> resT.sex <- mt.maxT(dat, sex[sex.na], test = "t.equalvar", B = 1000)
```

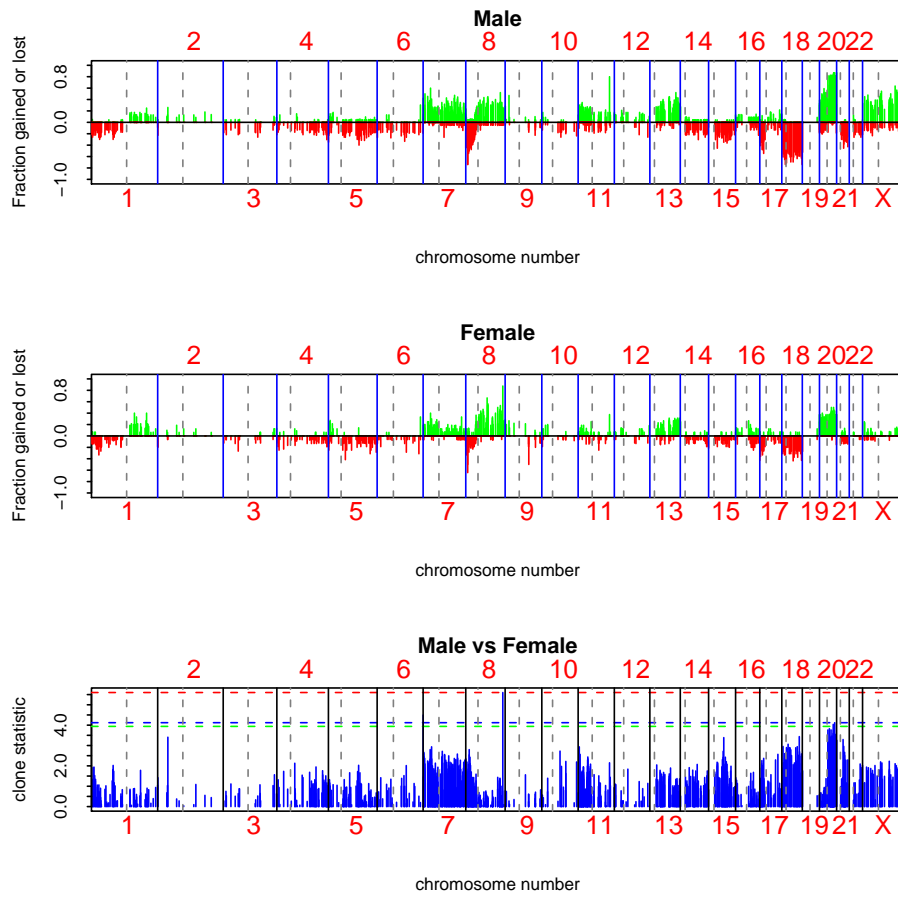

Figure 8: Frequency plots of the samples with respect to the sex groups for clones gained or lost in at least 10% of the samples

Testing association of clones with censored outcomes.Since there was no survival data available, we simulate data for a simple example to demonstrate creation and usage of basic survival object. We create an object equivalent to resT object that was created earlier. In the figure the samples are seprated into dead and alive/censored groups for ease of visualization. Nevertheless, statistic is computed and assessed for significance using proper survival object.

```
> time <- rexp(ncol(colorectal), rate = 1/12)
> events <- rbinom(ncol(colorectal), size = 1, prob = 0.5)
> surv.obj <- Surv(time, events)
> surv.obj

3.12   Clustering samples

Here we cluster samples while displaying phenotypes as well as within phenotypes using
chromosomes 4, 8 and 9 and display the phenotype labels, in this case, sex. We also indicate
high level amplifications and 2-copy deletions with yellow and blue colors. (fig. 11).

```
> par(mfrow = c(2, 1))
> clusterGenome(colorectal.na, response = sex[sex.na], titles = c("Female",
+      "Male"), byclass = FALSE, showaber = TRUE, vecchrom = c(4,
+      8, 9), dendPlot = FALSE, imp = FALSE)
> clusterGenome(colorectal.na, response = sex[sex.na], titles = c("Female",
+      "Male"), byclass = TRUE, showaber = TRUE, vecchrom = c(4,
+      8, 9), dendPlot = FALSE, imp = FALSE)
```

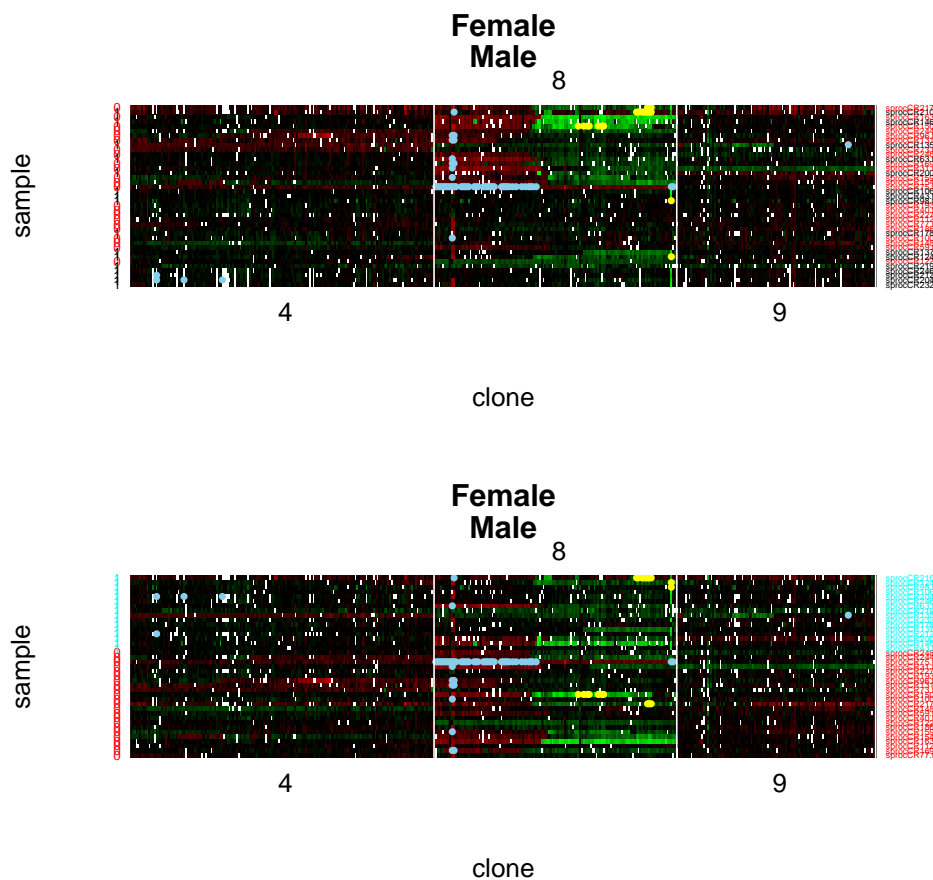

Figure 11: Clustering of the samples by sex
